Description

SHOCK-ABSORBING DEVICE FOR FOOTWEAR

BACKGROUND OF INVENTION

[0001] The present invention generally refers to footwear, and to a shock-absorbing system and device for footwear.

[0002] Under certain situations or working conditions, a person is compelled to be in continuous movement during many hours of the day, and in some cases, is more or less motionless. Since the comfort of the feet is more important, it is necessary to develop solutions including elastic suspension systems as well as footwear which provide greater comfort to the user.

[0003] For many years, shoe sole constructions have been developed that are capable of massaging the whole sole of the foot, since they are provided with cylindrical projections comprising rounded tips of the same or different heights, creating a resting surface according to anatomic requisites. It has been found, however, that in spite of the ef-

forts that have been made up to date, neither a uniform massage along the whole sole area of the foot nor a satisfactory support, which is suitable for the lower portion of the foot, have been obtained.

[0004] US Patent 3,722,113, issued on March 27, 1973 to K. Birkenstock, describes an article of footwear having uppers which may be in the form of straps, and a sole of yieldable elastomeric material. The article of footwear comprises on its lower surface projections which extend in a substantially perpendicular direction to the general plane of the respective surface of the article. The projections may be of different lengths.

[0005] Furthermore, the solution proposed in the patent document ES 2,116,430, belonging to the company Menghi Shoes- S.r.L of Italy, deals with a shoe sole, produced by means of molding, comprising a set of projections suitable for providing a massage to the sole of foot.

[0006] The above-mentioned solutions do not achieve the desired shock-absorbing, supporting and massaging action, since the projections suitable to support the foot do not have a design which allows to soften the pressure exerted by the foot over the displacement surface or the ground, nor a suitable height, nor the necessary arrangement to

allow the foot-exerted pressure to be effectively distributed, but rather concentrates it only in local points without achieving a uniform distribution thereof.

[0007] It is important to emphasize that a suitable massage action is produced when a constant change of the surface portions of the human anatomy is present, in this case in the foot subjected to the massage.

Summary of Invention

[0008] The present invention relates to a shock-absorbing device for use in footwear, comprising 1) a base having an upper surface adapted to confront the bottom surface of a user"s foot, and a lower surface adapted to contact a walking surface, 2) a plurality of first projections distributed on and projecting upward from the upper surface, and projecting in a normal direction to the bottom surface of the foot, and 3) a plurality of second projections distributed on and projecting downward from the lower surface; wherein the device provides a shock-absorbing system that is activated by the pressure exerted by foot flexion during walking on a walking surface, whereby the first projections are pressed in contact with the bottom of the foot.

[0009] The present invention also relates to a shock-absorbing

system for footwear, comprising a) a plurality of first projections distributed on and projecting upwardly from an upper surface, and in contact with and extending substantially in the normal direction to the bottom surface of a user"s foot, and 2) a plurality of second projections distributed on and projecting downwardly from a lower surface, and in contact with a walking surface, the second projections having a shape, and a circumferential recess, wherein the system is activated by pressure exerted on the second projections that, on foot flexion during stepping on the walking surface, cause the second projections to yield elastically and to displace and press the first projections into contact with the bottom of the user"s foot, thereby achieving a massage action, the shock-absorbing, and the uniform distribution of weight on the foot.

[0010] The present invention also relates to a footwear article, comprising: a). a shock-absorbing device for use in footwear, comprising: 1) a base having an upper surface adapted to confront the bottom surface of a user"s foot, and a lower surface adapted to contact a walking surface, 2) a plurality of first projections distributed on and projecting upward from the upper surface, and projecting in a normal direction to the bottom surface of the foot, and 3)

a plurality of second projections distributed on and projecting downward from the lower surface; wherein the device provides a shock-absorbing system that is activated by the pressure exerted by foot flexion during walking on a walking surface, whereby the first projections are pressed in contact with the bottom of the foot; and b) a shoe upper.

Brief Description of Drawings

[0011] FIGURE 1 shows a footwear article of the present invention having a shock-absorbing device.

[0012] FIGURE 2 shows a plan view of the upper surface of the shock-absorbing device of the invention that is in contact with the bottom surface of the user"s foot, having a plurality of first projections thereon.

[0013] FIGURE 3 shows a plan view of the lower surface of the shock-absorbing device of the invention that is in contact with a walking surface, having a plurality of second projections thereon.

[0014] FIGURE 4 shows a partial plan view of a first projection shown in FIG. 2, having raised members that contact the bottom surface of the user"s foot.

[0015] FIGURE 5 shows a cross sectional view of the first projection as viewed through line 5-5 of FIG. 4.

[0016] FIGURE 6 shows a lateral sectional view of the front end of the shock-absorbing device as viewed through line 6-6 of FIG. 3, illustrating the first projections and the second projections.

[0017] FIGURE 7 shows a lateral, sectional view of the heel end of the upper surface shock-absorbing device as viewed through line 7-7 of FIG. 3.

[0018] FIGURE 8 shows a longitudinal, sectional view of the heel end of the shock-absorbing device as viewed through line 8-8 of FIG. 2.

DETAILED DESCRIPTION

[0019] The present invention provides an improved shock-absorbing system for use in footwear, which provides a uniform shock-absorbing and supporting action, and a massage effect for the user"s foot.

[0020] As shown in *Fig. 1*, the instant invention also provides an improved footwear article *10* having a shoe upper portion *14* and a shock-absorbing device *12*, the production and sales price of which are relatively economical.

[0021] The present invention also relates to a shock-absorbing system that comprises an upper means adapted to confront the bottom surface of the user"s foot, and an opposed lower means adapted to contact with a walking sur-

face. The shock-absorbing system can be embodied in a shock-absorbing device *12* that comprises a base *16* having an upper surface *18*, shown in FIG. 2, that confronts the user"s foot (not shown), and a lower surface *20*, shown in FIG. 3, that confronts the walking surface (not shown). The device *12* comprises a plurality of first projections *22* distributed on and projecting from the upper surface *18* facing the user"s foot, extending substantially in a direction normal or perpendicular to the bottom surface of the user"s foot. The system is activated by the pressure exerted on a plurality of second projections *24* provided on and projecting downward from the lower surface *20* that contacts with the ground. These second projections *24* typically have the same geometric shape and size within an embodiment, as shown in the embodiment shown in *FIG. 3*, though they can have a different geometric shape and cross sectional size from one embodiment to another. Each projection *24* comprises a circumferential recess *30* that permits elastic movement between the base *16* and the lower projection *24* in response to an upward displacement of the second projection *24*. The first or upper projections *22* mechanically communicate with the second or lower projections *24* through the common base *16*.

When the flexion of the foot is produced during the displacement on the walking surface or ground, the upper displacement of the second projections *24* press the distributed first projections *22* on the upper surface *18* into contact with the bottom of the user"s foot. The first projections *22* displace in a plurality of directions, and typically all directions, thus achieving the massage effect, the shock-absorbing effect and the uniform distribution of the weight on the foot.

[0022] The invention further relates to a footwear article *10* that comprises the shock-absorbing system of the invention incorporated into a footwear upper *14*. An embodiment of the footwear article comprises the shock-absorbing device *12* and the footwear upper *14*. The footwear article can comprise a shoe, a slipper, a sandal, or any other article worn on the foot.

[0023] In an embodiment of the present invention, the first or upper projections *22* can comprise a ring of four raised members *26*, separated by four recesses *28*, as shown in *FIG. 4*. The first projection *22* also comprises a central pin *34*.

[0024] Amongst the plurality of first circumferential projections *22* are positioned, in a random manner, a plurality of, and

in a particular embodiment, approximately seventy-five pivots *32* that increase the massage action.

[0025] In FIG 3, the second projections *24* are shown as circular projections of the same size.

[0026] On the heel end of the footwear article, the shock-absorbing action is produced by a plurality of laterally-aligned elements, shown as a plurality of shorter upright wave-like walls 44 and a as a plurality of taller upright wave-like walls 42. By laterally-aligned means a direction between one side to the other side of the foot. The upright wave-like walls 42 and 44 are arranged in a plurality of laterally-aligned rows, with the shorter and taller walls members alternating in order, and channels 46 are alternately and confronting one another in a longitudinal direction. The rows of walls are separated in the longitudinal direction by a plurality of channels 46. The construction allows the flexion and torsion of the foot in the heel portion, following the shape of the walking surface or supporting ground. The laterally-aligned rows of wall elements are separated by a distance of typically about 6 mm. The wave-like wall elements 42 and 44 become compressed as a reaction to the foot torsion produced during walking, allowing thereby the flexibility of the foot.

[0027] The shock-absorbing system and device *12* of the invention are not limited to an exact number of either first or second projections *22* and *24*, respectively. The number of the projections used basically depends on the footwear size. In the embodiment shown in FIG. 3 the lower, front end of the device *12* (where the ball of the user"s foot is positioned) has eighteen of the second projections 24, while there are eight in the heel end.

[0028] An embodiment of the shock-absorbing device *12* typically comprises seventeen to twenty-one of the first circular projections *22* on the upper surface 18. As illustrated in the embodiment of FIG. 2, each projection *22* can comprise four raised members 26 with an approximately 3 mm separation or recess *28*, and a central pin *34*. The embodiment also comprises seventy-five individual pivots *32*.

[0029] The number of rows of the wave-like wall elements 42 and 44 located in the heel portion of the device 12 can range from about twelve to about twenty rows. More typically there are about seventeen rows, defining there between about sixteen wave-like channels *46*.

[0030] The massage mechanism is based on the reflexology science, wherein each point of the sole device represents an area of the body. During walking, pressure is exerted and

thus provides the massage of specific and well-defined areas. It is a known fact that foot massage is beneficial to stimulate and increase blood circulation, which sometimes can be unsatisfactory in peripheral joints of the body, especially in the feet, particularly when enclosed by footwear. This is particularly the case during working situations, where a person may be in continuous movement during many hours of the day, and in other cases, is more or less motionless. The plurality of first projections can be positioned on the upper surface whereby the projections are uniformly distributed, or are positioned in groups of projections according to the reflex points located in the sole of a user"s foot.

[0031] The elastomeric material of the shock-absorbing device is typically vapor pervious, comprising a plurality of microscopic orifices or pores (not shown), which allow vaporous exudates such as moisture and air to pass therethrough and between the lower surface 20 to the upper surface 18. The device 12 is internally designed such that a plurality of conduits are formed represented by the recesses 28 and other microscopic openings between the projections *22* and the pivots 32, as well as the wavy channels *46*, creating an air chamber between the upper surface 18 and

the bottom of the user"s foot. The air chamber can accumulate, retain and transfer the vaporous exudates. The contained exudates can then dissipate to the outer surface of the footwear through the vapor pervious base *16*. This improves the breathability and comfort of the footwear comprising the shock-absorbing device *12*.

[0032] The shock-absorbing system and device *12* can be made of rubber or other materials, such as polyurethane, TR with salp, TR with polyurethane, TR and TR with sole, where TR means thermoplastic rubber, a relatively new synthetic rubber, which combines the good properties of vulcanized rubber with the processing advantages of thermoplastics, such as polyurethane.

[0033] By applying the suitable composition in the manufacturing of the device, it is possible to balance the elasticity of the used material with that of the movement of the foot.

[0034] In the final assembling of the footwear, and in order to achieve a greater comfort for the foot, an intermediate layer (not shown) can be placed onto the upper surface *18*, between the device *12* and the shoe upper *14*. The intermediate layer can be made of natural materials such as carbon, felt or cotton.

[0035] The shock-absorbing device and system of the instant in-

vention can be used in a footwear article to not only provide an elastic cushioning and suitable support for the foot, but further to provide a foot massage on continually changing points on the foot, the footwear being lighter as well as more economical to produce or to manufacture.

[0036] The instant invention is based on the achieving of a uniform and suitable massage of the foot sole, since the defined profile of the upper, first projections in mechanical communication with the lower, second projections, closely correspond to the profile of the sole of the foot, such that not only the central part of the foot is supported by the projections, but also the side or marginal portions thereof.

[0037] It should be considered that the specification as well as the set of claims describes a preferred embodiment of the shock-absorbing device and the footwear article of the invention. It is possible, however, to introduce obvious modifications thereof, including different heights of the projections, dimensions, quantity, and designs both of the upper projections and the lower projections, without departing form the spirit and the scope of the invention, according to the following claims.
